Nkkokobe Local Municipality.

ABSTRACT

This paper investigated institutional factors influencing vegetable production in six small-scale vegetable projects in Alice town in the Nkkokobe Municipality of Eastern Cape of South Africa. Amidst worsening poverty in the wider society it was the intention to know how vegetable production can contribute to enhancing food security and if it is in a position to do so. Seeking some insights on effectiveness of the agrarian reforms on smallholder farmers in South Africa, the objectives of this study were to identify and explore institutional factors that influence vegetable production. The data were drawn from 62 farmers in the projects investigated. Descriptive analysis and binary logistic regression were employed to analyze the data and explain the patterns of interactions among the identified institutional factors influencing vegetable production. The study results revealed that some institutional factors need to be addressed to enhance vegetable production. The binary logistic results show that formal rules and informal norms are important in vegetable production. The most significant institutional variables revealed by the analysis were attributes of the formation and organizational structure of the projects, land tenure, extension service, collective action in production and marketing. The findings suggest that institutional change in respect to aforementioned variables and other complementary institutions such as contract farming and credit access can significantly contribute to increased, efficient and sustainable vegetable production.

INTRODUCTION

In the literature it has been affirmed that institutional factors (both formal and informal norms) influence and shape the way individuals interact in economic activity (Williamson, 2001 and North, 1993). This would normally influence the costs of production and or exchange (Lal, 1999; Coase, 1992 and North, 1993). Besides, according to North (1993), the development strategy of any country is embodied within the way societies view and interpret the world around them. Since formal rules are designed and implemented by human beings, an analysis of institutional factors is necessary to gain understanding existing institutional arrangements that would contribute to improved livelihoods and hence economic development (Adebeyi and Obasa, 2004). Brown (2000) also supported this view by postulating that development is not based on how much one has but on how much one does with what he/she has. It is, therefore, not surprising why positive policy reforms have been a success in other countries but a failure in others.

***Corresponding author: Rantlo, A.M.,**

Department of Agricultural Economics, National University of Lesotho, Roma180, Lesotho.

The assertion that sound policy reform is a function of the interdependency of formal rules and informal norms (Hou and Smith, 2009) comes quite handy to policy makers or development practitioners as they grope their way through the difficult and uncertain policy terrain right from the policy formulation stage to the implementation processes. Besides, institutional factor analysis studies have received special attention in natural resource management (Mokhahlane, 2009; Kirkland, Hunter & Twine 2005), marketing management and agricultural production costs (Jariand Fraser, 2009; Lal, 1999; Coase, 1992 and North, 1993).

An integrated holistic approach that seeks to address agricultural challenges should therefore be viewed as that which includes institutional factor analysis on specific agricultural enterprises with special reference to both production and marketing outcomes. Rightly observed, when smallholder farmers are faced with high transaction costs they resort to produce mainly for home consumption (WFP, 2009) but Randela (2005) also noted that even the size of a household has an influence in providing an incentive for economic activity decision making.

In addition to the interdependent nature of production and marketing institutions claimed by Coase (1992), it is likely that a number of 'new' emerging institutional factors call for special attention. In South Africa it has been claimed that developing markets for smallholder farmers can significantly attract them into the mainstream formal marketing, thereby being encouraged to increase production (Jari *et al.*, 2009 and Jacobs, 2008). A linkage of the working mechanism of production and market institutions is no doubt necessary in this regard. As IFPRI (2006) and North (1993) assert, economists still know very little about the dynamics of institutional changes. In support of this, Hou and Smith (2009) cautioned that the effects of informal norms (as a bridge between formal rules and governmental policy outcome) should not easily be undermined for positive policy reform. This is the case in view that the dynamics of informal norms are not easy to understand as they take time to change and that the very same formal rules themselves (Obi, 2011; Hou *et al.*, 2009 and IFPRI, 2006) are implemented via informal norm interpretation by policy makers or government officials.

For South Africa where a number of policy shifts have occurred since 1994 aimed at uplifting the previously deprived Black farmers, these considerations assume exceptional significance. Such policy shifts included with them some programmes such as market deregulation, Land Redistribution for Agricultural Development, the programme of black economic empowerment in agriculture known as Agri-BEE, the Comprehensive Agricultural Support Programme (CASP) and Micro-Agricultural Finance of South Africa (MAFISA). In one way or the other they were all aimed at increasing production, productivity and market access by smallholder farmers. Why progress has remained at inadequate levels is sufficiently confounding that immediate response was mandatory. At the same time, policy makers have to grapple with new issues such as the impact of climatic change, forces of international trade due to globalization some of which have triggered off the rising food prices that came to a head in 2008 and still continuing. There is no denying that South Africa's smallholder farmers are more than ever faced with high risks and uncertainty both in production and marketing.

Besides, the influence of 'interaction' of proposed policy reforms and evolving informal rules and norms have most probably retarded progress in smallholder development initiatives. Perhaps the pace at which the formal rules change is not properly aligned with the rate of change in the informal norms: a misalignment has the tendency to disturb the institutional interdependency.

MATERIALS AND METHODS

Description of the study area

The study was carried out in the Lovedale1 & Lovedale2 Vegetable Cooperatives, Nompumelelo Farmers Association, Lower Gqumahashe vegetable Cooperative, Somxada Food Security Association and the Sigabuliamatathenga Vegetable Cooperative of Alice town in the Nkonkobe Local Municipality. The Nkonkobe Local Municipality falls under Amatole District Municipality of the Eastern Cape Province.

Alice, a small town where UFH is situated, lies within the geographical position of latitude 32° 56' south and longitude 26° 50' east in southern South Africa in Eastern Cape Province. Alice town, where the six projects investigated are situated, is about 120 kilometers northwest of East London. Approximately 74% of the people living within Nkonkobe Local Municipality area are highly affected by poverty (Nkonkobe Municipality, 2009). The majority of the population which is about 61% resides in rural areas, 20% of the population resides in farms and scattered settlements (Nkonkobe Municipality, 2009). Alice has a population 65 472 individuals. The climate varies from hot in summer to extreme cold in winter with heavy frost and snowfall along the hilly areas. Average annual rainfall is 640mm, and most rain falls during the summer months from October to March, with frost and sometimes snow in winter. Mean maximum monthly temperatures range from 4°C in July to 38°C in February. Most of the roads linking the rural settlements are generally in poor conditions. The vegetation type is mostly Thorn Bushveld dominated by acacia Karroo species.

Framework for the Study

The study entailed both qualitative and quantitative approaches. The objective was to seek an explanation outside conventional production economics for the sluggish performance of the vegetable production of smallholder farmers that perpetuates their poverty and food insecurity. The main reason to look outside conventional economics research principles and concepts is that a large body of research already exists which have failed to come up with adequate explanations for the paradox of the unrelenting poverty despite the clear and unmistakable emphasis that has been placed on rural development, community empowerment, poverty alleviation and rural employment. There clearly must be issues that have escaped the attention of conventional and neo-classical economics which are influential enough to sustain the current disadvantages.

The new institutional economics has been helpful in filling the conceptual gap in situations such as this. Some of the distinguishing characteristics of this approach include the range of variables that are modeled that are often calibrated on the basis of qualitative attributes. This paper therefore assumes a model of economic performance of vegetable farms that is heavily influenced by such qualitative attributes as management capabilities through committee involvement in production and marketing decisions, the membership of farming groups, extension contacts, among others. This perspective incorporates the transactions cost idea of Coase (1960) in which the cost of doing business is seen as a binding constraint. This is no more true than in the smallholder contexts that characterize the former independent homelands where poverty is rife and even the most basic services can be inaccessible to the small farmer.

Data Collection

Data were collected using a structured questionnaire. Farmers in six vegetable projects were interviewed through various questions covering institutional factors influencing vegetable production in the study area.

To ensure that all questions were attended to by the respondents, the personal interview approach was used.

Sampling techniques and designs

A purposive sampling design was used. This is a non-probability sampling method whereby the researcher purposively interviews individuals meeting the criteria of interest with the hope that they will provide in-depth information required for the research project (Leedy *et al.*, 2005). To remove the element of bias, particularly given the small size of the total farming population in that category, all participating farmers in each project were interviewed (i.e. 5 from Lovdale1, 6 from Lovedale2, 5 from Sigabuliamatythenga, 13 from Somxada, 14 from Nompumelelo and 19 from Gqumahashe).

Data analysis

Data were coded in Microsoft Excel and then exported into SPSS (version 19) for analysis. In addition to the descriptive analysis to profile the smallholders and their socio-economic characteristics and production and marketing environments, the binary logistic regression operation was performed to test how institutional factors influence farmer's main reasons of producing vegetables. Binary logistic regression is useful when a dependent variable is dichotomous (Chan, 2005). The model according to Laio (1994) has only two categories in the endogenous variable resulting from a number of categorical predictor variables. The binary regression model has been widely used in a number of fields including social sciences when investigating the dichotomous response (Long, 1997 citing Trost, 1982). In the study area, it is assumed that a smallholder farmer is faced with two choices subject to institutional arrangement. A smallholder farmer strives to maximize his/her utility by either producing vegetables mainly for sale (considered to be fully commercialized) or for both sale and consumption (considered partial commercialized) subject to the prevailing institutional arrangement.

Using the binary logit model, Darroch and Clover (2005) also determined factors affecting the survival, growth and success of small-medium and agribusiness. Mohammed and Ortman (2005) had also used the binary regression model when investigating whether or not commercial dairy farmers were insuring their livestock. The model employed in this study is a binary model in the sense that it tests the probability that a smallholder farmer is influenced by institutional factors to either produce vegetable for both sale and consumption or solely for sale. Thus, in this study the binary response is set up which defines $Y=1$ for situations where a farmer produced vegetables for both consumption and sale and $Y=0$ where a farmer produced solely for sale. The model specification can then be written as shown in equation 1.

$$\ln(Y1) = \beta_0 + \beta_1x_1 + \beta_2x_2 \dots \beta_nx_n \dots \dots \dots \text{Equation 1}$$

$$\ln(Y0) = \beta_0 + \beta_1x_1 + \beta_2x_2 \dots \beta_nx_n \dots \dots \dots \text{Equation 2}$$

As shown in equations 1 and 2, there are two probabilities with Y_0 denoting the lower response category (Vegetable production mainly for sale) and Y_1 representing the higher response category being when a smallholder is producing for both sale and consumption.

Both equations present the outcome of the logit transformation of odd ratios which can compactly be represented as:

$$\ln(Y0/Y1) = \beta_0 + \beta_1x_1 + \beta_2x_2 \dots \beta_nx_n \dots \dots \dots \text{Equation 3}$$

Equation 3 allows for its estimation as a linear model for which the following definitions apply:

β_0 = the constant or intercept term of the regression model

$\beta_1, \beta_2, \beta_n$, = the regression coefficients of the individual predictor variables

$x_1 + x_2 \dots \dots x_n$ = Explanatory variables

Table 1 depicts the variables included in the model and the expected sign of such variables as they influence the dependent variable.

When the above variables are fitted in the model in equation 1, a typical regression model would be as shown in equation 2

$$\ln(Y0/Y1) = \beta_0 + \beta_1MCMF + \beta_2MCS + \beta_3MCW + \beta_4IAF + \beta_5LO + \beta_6WSF + \beta_7WSM + \beta_8PBS + \beta_9CR + \beta_{10}RM \dots \dots \dots \text{Equation 2}$$

Where:

Y_0 = Vegetable production mainly for sale

Y_1 = vegetable production for both consumption and sale

β_0 = Constant

$\beta_1 \dots \beta_{10}$ = Co-variants

RESULTS AND DISCUSSION

The results are presented separately for the descriptive analysis and the inferential analysis.

Results of the Descriptive Analysis

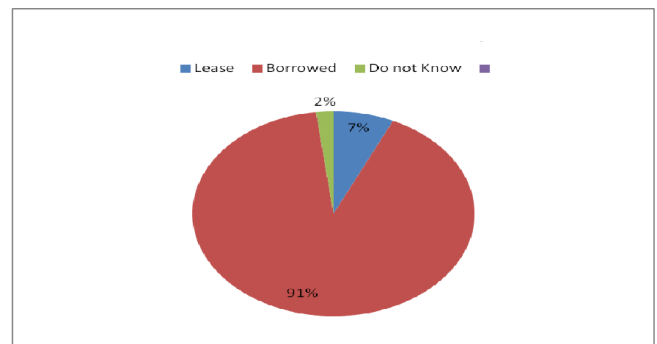

Characteristics of sampled household such as gender, age, marital status and educational levels attained were analyzed. The rationale for the inclusion of the demographic features is that demographic characteristics of households are essential when analyzing economic data because such factors would influence the households' economic behavior. Demographic features of sampled household are most likely to influence their production levels and as such are relevant. Table 2 exhibits the demographic characteristics of the sampled households in the study area. The six projects investigated were Siga, Lov1, Lov2, Somxa, Nompu and Gquma. Comparing the age distribution across all projects, Nompu and Gquma have been exceptionally unique with the dominating age group of 66-75 years with 43% and 37%, respectively. The results also show that it was mainly in Nompu and Gquma where the age distributions by respondents have been evenly distributed, implying that not only old aged persons engage in vegetable production. The dominant age group by the distribution of the respondents (26%) across all projects surveyed ranged from 36-45 years. Interestingly, male farmers represented a higher percentage (71%) of the projects participants.

This finding may most probably be explained by a high retrenchment rate of men from the mining sector in South Africa. The majority of sampled farmers were married in all projects except for Siga where 60% of farmers were single. All in all, the dominant percentage by marital status was 61% of the married project participants in all projects as shown in Table 2. The results presented in Table 2 further show that most project participants (40%) from six projects had a high school education. According to Table 2, farming plays a central role in farmers livelihoods as 90% of all the farmers surveyed were fully employed in farming.

This finding can best be explained by the fact that in Nkonkobe Municipality, unemployment rate is high (Nkonkobe Municipality, 2004). The Organizational structure of the projects was also investigated. By organizational structure, the study investigated whether or not the projects members had the management committees that oversaw the projects' operation and took decisions about resource allocation and distribution of tasks and responsibilities. The descriptive analysis on organizational structure of the projects revealed some interesting results on strengths and weakness from the point of view of the projects participants. Table 3 presents results of the values of the strengths and weakness of the management committees of the enumerated projects. The research findings show that the management committees motivated members in all six projects. In general, motivation and dispute resolution amongst the project members seem to have been the common strengths reported in all six projects This finding seems to support the evidence from the literature that local communities have their own complex informal mechanisms for resolving their conflicts (IFPRI, 2006). Flowing from the strengths of the management, the survey farmers were also asked to pinpoint the weakness (if any) of their management committees. Table 3 presents the distribution of the respondents by the weaknesses of their respective management committees.

Based on respondents 'perceived' weakness of their management committees, the research findings show that lack of negotiation power to lobby formal markets, which by virtue they entrusted on their management committees, seem to be common across all projects. The evidence from the literature, that institutional factors have tended to constrain smallholder's access to formal markets, is supported by this finding (Magingxa et al., 2009; Jari et al., 2009 and Jacobs, 2008). More weaknesses than strengths were identified by farmers in each project. In an attempt to predict the sustainability of each project, survey household were asked where the idea of forming the cooperatives came from. In Siga, 100% of farmers reported that the idea came from members themselves. In Lov1 and Lov2, 100% of respondents mentioned that University of Fort Hare pioneered the formation of the association. ARDRI (Agriculture and Rural Development Research Institute at the University of Fort Hare) was reported (by 100% of the respondents) as the body that had broached the idea of cooperative formation in Gquma. In Nompu and Somxa, survey household provided different responses on who brought the idea of project formation. The issues of who pioneered farmer's association projects seem to be critical as revealed by the binary logistic results and as such may open the scope for further research to determine the productivity

and sustainability of such projects. Given the fact that FAO (2009) argues that ownership of farm land would affect the sustainability of the land use, the survey farmers were asked how they accessed the land they farm with. Generally, the research findings revealed that most of the land used for vegetable production is not owned by the project participants. Figure 1 illustrates different ways through which land was accessed in all projects. The research findings, with regard to land ownership and or land access, indicate that the land reform program me, in particular the tenure systems, has not yet fully addressed the problems of the previously deprived black smallholder farmers in South Africa.

Figure 1. Land Acquisition Strategy in Six Vegetable Projects (n=62)

Empirical Results of the Binary Logistic Regression

It is hypothesized that smallholder farmers are influenced by institutional factors in vegetable production. The assumption is that a smallholder farmer aims to maximize his or her utility by either producing vegetable mainly for sale and consumption or mainly for sale subject to institutional constraints in the Nkonkobe Local Municipality. Nine institutional variables and one technical variable (CR) were factored in a binary logistic regression to test their influence on farmer's main reason for producing vegetables.

Such variables modeled include: management committee meeting frequency (MCMF), Management committee strength (MCS), management committee weakness (MCW), idea of association formation (IAF), land ownership (LO), working strategy on production in the field (WSF), working strategy in marketing (WSM), presence of an extension service (PES), Condition of roads (CR) and relationship to the Municipality (RM) by the survey farmers. Seven of such variables were significant at 5 percent alpha level in influencing the farmers 'main reason for vegetable production (see Table 4). The higher the value of the odds ratio for each variable in Table 4, the higher probability that such a variable would change to either direction (i.e. vegetable production mainly for sale or for both consumption and sale) if adjusted otherwise. The p-values <0.05 show the significance of each variable in influencing the vegetable main production reason by the surveyed farmers. Further interpretation of the results in Table 4 is made for each variable in the next subsection.

$$\ln(\text{mainly for sale/For sale \& consumption}) = 10.290 + 5.752(MCMF) + 0.612(MCS) + 0.537(MCW) + 0.971(IAF) + 0.889(LO) + 6.222(MSF) - 2.591(WSM) + 2.855(PES) + -1.484(CR) + 1.310RM$$

Table 1. Summary of Modeled explanatory variables

Variable name	Variable label	Coding	expected sign
Management committee meeting frequency	MCMF	0 if more frequent, 1 otherwise	+/-
Management committee strengths	MCS	0 if many, 1 otherwise	+
Management committees weakness	MCW	0 if no, 1 otherwise	+/-
Idea of association formation	IAF	0 if participants, 1 otherwise	+/-
Land ownership	LO	0 if participants, 1 otherwise	+
Working strategy in the field	WSF	0 if collectively, 1 otherwise	+
marketing strategy	WSM	0 if collectively, 1 otherwise	+/-
Presence of extension service	PES	0 if yes, 1 otherwise	+/-
conditions of roads	CR	0 good, 1 otherwise	+
Relationship to the municipality	RM	0 if good, 1 otherwise	-

Frequency of management committee meetings

Frequency of the management committees meeting seems to have a strong influence on farmer's main reason to produce vegetables. The logistic results presented in Table 4 reveal that an increase in the frequency of the management meeting can significantly influence farmers working in projects or associations shift their main aim of vegetables production towards the lower base response variable (i.e. mainly for sale). This demonstrates the urgency to disseminate information on cultural practices and also capacitate farmers to acquire skills and know-how. It is however important to note that despite the significance of this variable in influencing the farmers' decision in vegetable production, the complementary nature of other market institutions is a key for viability of the farmer's decision in this respect.

Idea of association formation

There is a weak relationship between the main reason by farmers to produce vegetables and who initiated project. The logistic results presented in Table 4 show that if the ideas of project formation was or is initiated by the project participants, it is highly possible that they would align their production decisions towards a high base response variable (i.e. vegetable production for both sale and consumption).

their production decision towards a high response variable being for both home consumption and sale. In this respect, even if the essential infrastructure required for commercialization were to be put in place, it could have still been somehow hard for smallholder farmers to be fully commercialized owing to the lack of land ownership. When farmers lack title to the land used for farming, they resort to making short term production decisions since they could feel that they are not stable on such land (FAO, 2009). The results of land ownership in this regard, suggest that whether or not a farmer has access to the market, he could be fully commercialized when he holds title to the land used.

Working strategy in the field

Farmers working collectively can pool together some resources thereby securing more produce for the market (Chikazunga, undated). The prior expectation was that positive relationship between vegetable production for sale and the collectively operating projects would exist. However, the results presented in Table 4 reveal that collectively working farmers are influenced to produce vegetables for both sale and consumption. Given the high significance level of this variable ($p=0.002$), the result suggests that when farmers work collectively in the field there is greater probability that they produce vegetable for both sale and consumption.

Table 4. Results of the logistic regression analysis

Parameter	Coef.	S.E.	Wald	P-value	Exp (B)
Constant	-10.290	5.184	7.102	0.47	0.000
Management Committees Meeting frequency	-5.752	2.158	1.397	0.008**	0.003
Manangement Committee Strengths	0.612	0.517	2.604	0.237	1.843
Management Committee Weakness	0.37	0.333	3.860	0.107	1.710
Idea of association formation	0.971	0.494	4.707	0.049**	2.640
Land Ownership	0.889	0.410	9.838	0.030**	2.432
Working strategy in the field	6.222	1.984	5.249	0.002**	503.858
Working Strategy Marketing	-2.591	1.131	3.888	0.022**	0.075
Presence of Extension Services	2.855	1.448	1.539	0.049**	17.373
Condition of Roads	-1.484	1.196	4.027	0.215	0.227
Relationship with the Local Municipality	1.310	0.653	3.940	0.045**	3.707

This finding shows that in situations where farmers are engaged in project identification and formulation, they tend to be flexible in planning the production decisions subject to resources, technical and institutional constraints given the fact that two options are possible in a high base response category. This finding may best explain why imposed or top-down projects have had little successes of sustainability in improving livelihoods. This is likely the case when participants are supposed to work within the expectations of project pioneer(s). As with other variables, it must be acknowledged that a farmer's main reason to produce vegetables could also be influenced by other factors such as market access and family size (WFP, 2009 and Randela, 2005), further highlighting the need to adopt a broad analytical perspective that combines conventional neo-classical tools and institutional economics.

Land ownership

Land ownership seems to have a strong influence on farmer's main reason of vegetables production. At 5 percent significance level, the results in Table 4 show that if farmers do not have title to the land they farm, they are likely to shift

It is more likely that this occurs as people working together have different aspirations (Brown, 2000).

Marketing strategy

It is argued that collective marketing improves market access by smallholder farmers (Jari *et al.*, 2009 and Jacobs, 2008). The -2.591 coefficient of this variable in the logistic model represents the likelihood that collective marketing would influence smallholder farmers to shift their main reason for producing vegetables towards a lower base response variable (i.e. mainly for sale). The significance of this variable ($p=0.02$) in influencing farmers main reason for producing vegetables clearly justifies the strengths of the variable and show that farmers marketing their produce individually are less likely to produce mainly for sale.

This finding thus supports that of IFPRI (2006) postulating that collective action helps farmer access markets which they individually could not access. It can be inferred from this finding that those farmers marketing individually would shift towards vegetable production for consumption and sale in which case the degree of market access would be minimal due

to higher transport costs and lack of social capital (Chikazunga, 2007; Jari *et al.*, 2009 and IFPRI, 2006).

Presence of an extension service

Based on logistic results presented in Table 4 the relationship seems to exist between the farmer's main reason for vegetable production and the delivery of an extension service to farmers. The delivery of an extension service seems to influence farmer's main reason to produce vegetables mainly for sale and consumption given the coefficient of 2.855. The implication of this coefficient in the logistic regression mainly reflects the strengths of this variable in influencing vegetable either way (i.e. for consumption and sale or for sale only). It seems that absences of an extension service would then influence farmers to produce vegetable mainly for sale. It is most likely that the current extension services provided to farmers are mostly oriented on subsistence food security assurance with farmers selling only the surplus. The fact that FAO (2007) has discovered that the extension workers rarely if ever plan the work along marketing challenges faced by farmers may best explain why it seems from the results that the absence of extension service would influence farmers produce for both sale and consumption. Nevertheless, it cannot be concluded with certainty that the absence of extension services would always influence farmers to produce vegetables mainly for both sale and consumption. What this result implies in practice is that the current extension service provided to farmers needs to be reviewed such that it orientates the smallholder farmers to marketing issues. *Ceteris paribus*, it is most likely that most of the smallholder farmers would be fully commercialized (i.e. producing vegetables mainly for sale) given an enabling market environment.

Reasons for the kind of relationship with the Municipality

The results presented in Table 4 on reasons for the kind of relationship (normally based on perceptions as informal norms) of the project participants and the local Municipality influenced their main vegetable production decisions in the study area. The logistic results show that the current relationship of the project participants and the local municipality influenced them to produce vegetables for sale and consumption at ($p=0.045$). Given its significance in the model, this variable (based on perceptions) if adjusted to the other direction could influence farmers produce mainly for sale. This is especially true in view of the fact that Hou *et al.* (2009) cautioned that the influence of informal norms, as a bridge between formal rules and policy outcome, should not be undermined. It must, however, be noted that changing of norms and perception would require strategic approaches, such as provision of incentives or penalties, given the fact that they take time to change.

Summing up the Evidence

In the Nkonkobe Local Municipality nine institutional factors were identified and analyzed on the basis of their influence on small-scale vegetable producers' decision. Of all such factors identified, the frequency of the management committees meeting was significant in shaping the farmers' decisions in vegetable production.

As the management committee convenes meetings frequently, there are increased chances that project member would produce mainly for sale. An issue of who brought up the idea of project formation was also significant to the extent that it influenced farmers to produce vegetables for sale and consumption. Given the fact that there was confusion as to who pioneered association formation in most projects, it is most likely that commercialization policies (i.e. as hypothesized to represent mainly for sale) are likely to be a success if farmers initiates their own projects. On the other hand land ownership in the study area seemed to be a subject of concern as the majority of farmers (see Figure 1) were farming on leased land. The inferential statistics suggests that in the absence of secure land tenure, it is most unlikely that farmers would be fully commercialized (i.e. production mainly for sale). Similarly, the results of the study revealed that different types of collective action must be noted in policy formulation and or recommendations. This is especially the case in view of the fact that farmers who worked collectively in production were influenced to produce for both sale and consumption but those who marketed the produce collectively were influenced to make production decisions that are inclined more towards sales.

Consequently an argument that collective action in marketing can help make farmers access more rewarding markets seems plausible (Jari *et al.*, 2009 and IFPRI, 2006). Presence of an extension service to the farmers does not necessarily mean farmers would be influenced to produce mainly for sale. In the projects investigated, most farmers received an extension service but such a service influenced them to produce for both sale and consumption. This could most probably be explained by the fact that extension workers seldom address marketing opportunities and challenges to farmers (WFP, 2009). The relationships with the local municipality influenced farmers' production and marketing. Although such a relationship between the municipality and farmers is largely influenced by differing perceptions and political affiliations, the research finding suggests that if the very same perceptions and political positions change in the opposite direction, it is most likely that farmers would produce vegetables mainly for sale or be fully commercialized. Therefore, strategies proposed in linking smallholder farmers to profitable markets should take into account the role the municipality could play in this regard. Perhaps, this is most likely the case given that the Municipality has responsibility for the provision of basic market access requisites such as roads and market information among others.

Given the fact that institutional factors influence production and marketing costs (Lal, 1999; North, 1993 and Coase, 1992), it is natural to expect that they would influence farmers' decisions to either produce for sale, consumption or for both. This is especially true as discovered by WFP (2009) that when smallholder farmers fail to access more profitable markets, they normally resort to produce mainly for home consumption. Nevertheless, Monde (2003) and Randela (2005) had cautioned that own agricultural production for home consumption should not be easily undermined as it contributes to improved household food security. The fact that most of the surveyed farmers did not have secure tenure rights and that the majority did not receive consistent visits from the extension

service could best explain why some land was left idle (i.e. in Somxa and Gquma for instance). Besides, sustainable and efficient land resources use is compromised when individuals lack secured tenure rights on the land use (FAO, 2009 and Makosholo, 2005). This raises a serious concern as about 90% of the survey farmers were using leased land across all six projects.

The problem statement for this investigation was that the institutional factors influence the way individuals interact in vegetable production and hence economic activity. The problem that needed to be examined was whether the existing or imposed formal rules on project participants do influence them to make production decisions that make them derive more benefits on sustainable and efficient basis in vegetable production. A number of institutional aspects identified influenced decision making in vegetable production by the survey farmers and it was observed that a limitation of one or more of the identified institutional factors is likely to outweigh the positive impact of the other institutional factors. Owing to the fact that most of the surveyed farmers confirmed that they lacked ownership of land, clearly signals retarded development and inappropriate land use practices. Factored in a logistic model, land ownership was significant such that the results showed that in the face of lack of ownership, farmers are unlikely to be fully commercialized.

Provision of title deeds to farmers is necessary for increased vegetable production and long-term productivity of farm lands. Similarly, the fact that the farmers who had relatively large land or plot sizes such as those in Somxa and Gquma (i.e. where some land was left idle during 2010/2011 growing season) explains that institutional support is needed and that exploiting the interdependency of institutional factors as well as the availability and suitability of the resources attributes is inevitable to developing smallholder farmers. Contract farming (though did not exist amongst all survey farmers) is crucial as a tool for enhancing smallholder farmers' market access based on the evidence from the literature. It encourages commercialization of agriculture and promotes the development of entrepreneurial skills among smallholder farmers (Kirsten and Satorius, 2002). Similarly, access to and use of credit by the survey farmers was investigated. None of the farmers in the study area had used credit. Given the evidence from the literature (FAO, 2009; Seibel, 2000; Swinnem and Gow, 1999 and Hoff and Stiglitz, 1990) and observation during field survey in 2011, the use of credit by smallholder farmers is low.

In this regard it is recommended that access to credit and its use (i.e. where farmers do not have alternative means of cash) could help farmers address problems of production inputs such as seeds, fertilizers, including irrigations facilities, storage facilities and transport (Salami, 2010). However, access to credit should be made on interest rate that smallholder farmers can afford while at the same time earning some income. It is in this sense that one notes that market access correlates with credit access because if farmers do not have the market to sell the produce so as to repay the loan then the financial institutions are reluctant to lend. The same applies to farmers who do not have collateral. The banks or financial institutions would be reluctant to give out loan (FAO, 2009).

Even those smallholder farmers who have collateral must be linked to markets (Jacobs, 2008). This could help enable a mutual benefit between the financial institutions and clients or farmers in economic activity. Generally, the analysis and discussion of the results have shown that when farmers are constrained by some institutional factors, the positive outcome of the existing institutional factors on smallholder farmers may not be realized. Therefore, for increased vegetable production in the Nkonkobe Local Municipality, a more involved immediate reconsideration of weak institutional factors identified is crucial. The availability and suitability of the physical resource attributes such as land including infrastructure are all crucial in complementing the effectiveness of institutional factors. Given the foregoing discussion, it is concluded that some institutional factors need be modified accordingly so as to complement the effectiveness of proposed agricultural policies in the study area. There is a need for institutional change more especially when development practitioners and farmers claim the commercialization of agriculture in the Nkonkobe Municipality.

Acknowledgements

I wish to thank everyone who contributed to the success of this paper. It would not have been possible without your input, time and support; I really appreciate it. Special thanks go to the people of Nkonkobe for the cooperation and patience during the survey part of this study.
