ABSTRACT

In Côte d'Ivoire, the Loranthaceae infect many wild and cultivated woody species. In the Sud-Comoé region, a study evaluating the level of infestation of Loranthaceae on woody species of agroecosystems showed that 115 host species distributed in 77 genera and 34 families are parasitized by the Loranthaceae. The families of the attacked host taxa are Caesalpiniaceae, Moraceae, Euphorbiaceae, Mimosaceae, Apocynaceae and Rutaceae. The results, show that the average infection rate is 37,94 p.c. (per cent) and intensity of infestation is 8,15 tufts/tree. Seven Loranthaceae species have been identified. *Tapinanthus bangwensis* is ubiquitous with greater frequency and abundance (39,84 p.c.) in the study area. Parasitism Loranthaceae is a scourge to be considered. It is therefore essential and urgent to develop a targeted control research program for fruit trees, source of income for farmers.

INTRODUCTION

The Loranthaceae are shrubs, chlorophyll hemiparasites who live on cultivated tree branches or not (Aké-Assi, 1984). Their presence on the branches of a subject, causes a decrease in the growth of the host individual. According Sallé *et al.* (1998), parasitic plants, once attached to the host branch through a sucker, takes water, minerals needed to develop on its hosts. Following the various climate changes as a result of ecological changes linked to the destruction of primary vegetation, became the Loranthaceae an ecological and agronomic problems (Kuijt, 1969) given the extent of the damage. Keeping in view the above facts, this work is a contribution to the knowledge and the effective fight against parasitism Loranthaceae on woody plants in agroecosystems.

MATERIALS AND METHODS

Study site

The study site chosen is the Sud-Comoé, an administrative area that covers an area of 800 km².

*Corresponding author: Amon, A. D. E.,
Laboratory of Botany, U.F.R. Biosciences, University Félix Houphouët-Boigny, 22 BP 582 Abidjan 22, Côte d'Ivoire

It includes three departments: Aboisso (5° 66 'and 5° 28' north latitude and 3° 12 'and 3° 20' west longitude), Grand-Bassam (5° 26 'and 5° 13' North latitude and 3° 44 'and 3° 58' east longitude), Adiaké (5° 28 'and 5° 21' north latitude and 3° 16 'and -3° 08' west longitude). The choice of this region is driven by a high frequency of Loranthaceae on trees and shrubs of agro-ecosystems. Average annual rainfall is 1500 mm. The annual average temperature is 27 ° C. The vegetation is characterized by small islands of forest, protected forests and anthropogenic formations (fields, plantations).

Materials

The plant material was composed of woody flora of agro-ecosystems and species Loranthaceae. The technical equipment includes a global positioning system (GPS), digital camera, binoculars, rope and ribbon-meter.

Methods

The work took place from 2007 to 2009. Investigations were carried out in agroecosystems of the Sud-Comoé region, particularly in cocoa and coffee farms. The farms were selected by a random draw, at random, based on the list of all

the plantations of cocoa and coffee, listed by the Departmental Directorate of Agriculture. The method of surface readings was used to collect data from the field. It was to delineate plots of one hectare each area (100m x 100m), arranged alternately at different places in the plantations. For a thorough floristic inventory, the plot was divided into strips 10 meters wide and 100 meters long. For a thorough floristic inventory, the plot was divided into strips 10 meters wide and 100 meters long. For band, parasitized and healthy individuals, the clumps of parasites parasitized on each individual were counted.

The collected data were used to determine: - rate of infestation (T_x) = (number of individuals infected / total number of individuals present) x100;

- intensity of infestation (I_i) = total number of tufts of Loranthaceae / number total individuals infested identified. Statistical analyzes of the results were made in Excel 5.0.

RESULTS

Floraagroeco systems inventoried

Table 1 shows the floristic composition of agroecosystems inventoried. There is a high proportion of fruit trees and bushes (avocado, citrus...) present in the plantations. In total, 115 species distributed in 77 genera and 34 families, parasitized by seven Loranthaceae species were inventoried. The seven parasitic species encountered are *Tapinanthus bangwensis* (Engl. K. Krause) Dancing (Figure 1), *Tapinanthus belvisii* (DC) Dancing, *Tapinanthus sessilifolius* var. *glaber* (P. Beauv.) Van Tiegh. (Figure 2), *Phragmanthera capitata* (Spreng.) Ballé (Figure 3), *Phragmanthera capitata* var. *alba* (Spreng.) Ballé (Figure 4), *Globimetula braunii* (Engl.) Van Tiegh. and *Globimetula dinklagei* subsp. *assiana* (Engl.).

Figure 1. Flowering Branches of *Tapinanthus bangwensis* (Engl. et K. Krause)

The data in the table show that over 12 086 individuals inventoried, 4 586 are infected (Table 1). The families of the

parasitized host species are Caesalpiniaceae (13 taxa, or 48,23 p.c.), Moraceae (10 taxa, or 29,41 p.c.), Euphorbiaceae and Mimosaceae each with 9 taxa (26,47 p.c.), Apocynaceae and Rutaceae taxa with 7 each, or 20,59 p.c.

Figure 2. Flowering and fruiting branches of *Tapinanthus sessilifolius* (P. Beauv) Van Tiegh

Estate of infestation of trees and shrubs identified

Regarding the degree of infestation, Table 1 indicates that the rate of parasitism varies host species. It is between 1,46 and 84,95 p.c. Attacked taxa include *Cecropia peltata* (84,95 p.c.), *Spondias mombin* (75,24 p.c.), *Acacia mangium* (71,42 p.c.), *Theobroma cacao* (67,27 p.c.), *Hevea brasiliensis* (58,18 p.c.), *Pycnanthus angolensis* (56,20 p.c.), *Cola nitida* (54,98 p.c.), *Funtumia elastica* (51,78 p.c.), *Anthocleista djalonensis* (50,98 p.c.), *Bombax buonopozense* (49,80 p.c.), *Gmelina arborea* (50 p.c.), *Rauwolfia vomitoria* (44,97 p.c.) and *Persea americana* (44,34 p.c.). As for the intensity of infestation, there in *Acacia mangium* (19,60 tufts/tree), *Hevea brasiliensis* (14,14 tufts/tree), *Tectonia grandis* (13,28 tufts/tree) and *Persea americana* (12,76 tufts/tree). Eleven well-known fruit species are variously parasitized by Loranthaceae in agroecosystems. Their infestation rate is between 1,46 and 58,33 p.c. These are in descending order, *Anacardium occidentale* (58,33 p.c.), *Cola nitida* (54,98 p.c.), *Persea americana* (44,34 p.c.) *Citrus grandis* (35,71 p.c.), *Citrus limon* (35,41 p.c.), *Citrus reticulata* (33,33 p.c.), *Citrus sinensis* (27,31 p.c.), *Citrus aurantium* (23,91 p.c.), *Annona muricata* (10, 22 p.c.), *Psidium guajava* (13,83 p.c.) and *Mangifera indica* (1,46 p.c.). Similarly, perennial crops have a parasitism rate of between 6,36 and 67,27 p.c. This is *Theobroma cacao* (67,27 p.c.), *Hevea brasiliensis* (58,18 p.c.), *Coffea arabusta* (10,51 p.c.) and *Coffea canephora* var. *robusta* (6,36 p.c.). Overall, about 12,086 individuals surveyed, 4,586 are infected. The average infestation rate is 37,94 p.c. and infestation intensity tufts 8,15/tree for the 115 individuals identified (Table 1).

Table 2 on parasitism Loranthaceae on this timber *Tapinanthus bangwensis* as the species most common (ubiquitous) and most abundant in the region, with an average number of tufts of 39,84 p.c. It is followed in the order descending by *Phragmanthera capitata* (24,7 p.c.), *Phragmanthera capitata* var. *alba* (17,61 p.c.) and *Tapinanthus sessilifolius* var. *glaber* (10,51 p.c.). Furthermore, *Tapinanthus belvissii* is the only species found in the littoral part of the study area (Grand-Bassam)

DISCUSSION

Seven species of Loranthaceae were inventoried and identified the 11 identified in the Ivorian forest zone (Balle and Halle, 1961).

This difference in number of species is due to the extent of the study area and the ecological environment studied. However, this number is higher than 5 species inventoried by Soro (2010) in orchards to the west. *Tapinanthus bangwensis* ubiquitous species, the most abundant of the seven parasitic species inventoried in agroecosystems of the region. This high parasitism *Tapinanthus bangwensis* also reported by Soro et al. (2004b) who say it is one of the most abundant parasites on Karités natural park Tengrela. *Tapinanthus belvissii* is encountered in the coastal part of the study area. These results were confirmed Amon (2006). The average rate of infection of woody hosts by Loranthaceae in agro-ecosystems is 37.4 p.c. This rate is higher than that obtained by Soro et al. (2009) which is 29,05 p.c. in Legumes test/cocoa trees in forest area of the Côte d'Ivoire. The results for the magnitude of the

scourge show that most of the known fruit trees (*Cola nitida*, *Persea americana*, *Psidium guajava...*) are parasitized by Loranthaceae. The parasitism of the fruit by Loranthaceae is confirmed by Dibong *et al* (2008 and Houénon *et al.* (2012). *Dolonix regia* and *Mangifera indica* resistant to parasitism Loranthaceae according to the literature were found infested (Boussim *et al.*, 1995; These results make us think that today there is certainly no Loranthaceae resistant species, but rather undiscovered species parasitized by hemiparasites.

Conclusion

Agroecosystems of the Sud-Comoé region of south-eastern Côte d'Ivoire are home to seven species of parasites. The degree of parasitism of wood in the study area by Loranthaceae depends guests. *Tapinanthus bangwensis* and *Phragmanthera capitata* are ubiquitous and the most abundant of the seven species of Loranthaceae inventoried. In view of the different degrees of attack and especially the socio-economic importance of certain fruit species attacked, an outreach program and a major struggle remain essential.
